

Brief description: Our project aims to develop a pill box that can notify users if they have medication that they have to take and may have missed because of a busy schedule or anything else.

1. Our tests will give us the information on how well the code works, how long the prototype would last until it stopped working, and if it would be small enough to store anywhere. When we tested out the code, we wanted to make sure that the hinge for the container would always register correctly, so nobody would get an incorrect time to take their medications, or if someone thought they already took their medication that day because of a fault in our code. While we were testing the screen, it didn't show the correct code display because it was a faulty screen, so we would choose a reliable resource next time.
2. Our testing procedure was...
 - a. Checking the lines of code
 - b. Running the display
 - c. Making sure there is enough room in each container for the medication.
3. (not applicable)
4. Our tests will give us the information we need to support our top 3 high priority requirements:
 - a. The box must be big enough to first all the user's medication.
 - i. We would take the average size of a pill and given how big our container sizes are, see how much medication we could fit into it.
 - b. The box must notify the user via displayed message.
 - i. We checked the code and ran the display message, proving that it does indeed relay the message.
 - c. The mechanics must fit into the box to optimize space.
 - i. Attached to the prototype there is a cardboard box made to hold the wires and mother board.
5. (not applicable)
6. Our testing plan would work considering how simplistic our concept is. This automated pill box should be able to relay reminders to the user, (step b. Running the display). And should be able to hold the required amount of medication for each day.
