

1. One other attempt to solve this problem can be making the handles longer and varied lengths.
 - a. We are trying to refrain from making the chariot extremely heavy, in order to maximize the speed that it moves at
 - b. Finding handlebars that are accessible to be connected may be expensive and there must be research done to find out what the best option is.

The positive aspects of each of these designs is that it is less material and uses less metal so it will not be as heavy and will be easier for the 8th graders to pull the chariot. They all only use one pole instead of the current design which uses two poles that are angled together as a triangle but have more metal poles in between. They are both much more simple designs which is good but the negative is that neither of them are as safe as the current chariot design because the cockpit sides are much smaller and aren't as supportive. Another negative about the chariot designs above is that the wheels are all wooden, which would be an ineffective design for our chariot as our chariot needs to run on wood chipped turf field.

2. We have met with Seggy and Mr. Bereta and both have not been helpful. We have gotten some information from Seggy with the fact of needing more treaded tires. This has caused us to be more creative and take initiative on our own to come up with new ideas and ways to improve the chariot.
3. We've especially found difficulty in how to improve the design based on the little information that we have on BMS's chariot, especially considering GFS has been continuously winning the Latin Day race over the past few years.
4. We met with maintenance and they told us we needed taller and tires with more tread

Insert picture of wheels once we get them
Insert pictures of the chariot now (on wed)
