

Part B

Other prior solutions included using many different layers and filters to try and get the water filtered

What worked:

Filters that use sand gravel and charcoal are good making removing dirtiness but not contaminants

Activated Carbon filters out more than sand gravel and charcoal

With lower concentrations these filters CAN work

Problems:

The activated carbon breaks down easy

Can be layered wrong meaning it just doesn't work

Can't take on big stuff or high concentration

Ways to improve: the best way to improve is trial and error, change the design, change the layering, materials, experiment and eventually you'll have to find a solution. Once a design has been found that's better than the last, improve on that and try and make it accessible to places that may not be able to get water easily.
