

Element C: Presentation and Justification of Solution Design Requirements

The best way to build the water filter would be to take the good things out of the ones that worked and combine them to make the best possible filter. An example would be taking the materials from one but getting inspiration for the design from another one.

The water filter that will be created must be able to filter out all of the dirtiness of the water as well as the chemicals and other things that might be in the water. It also must be able to do this in any environment that has water that can be filtered. It would be best to use things like activated carbon and sand in it with some other things as well as having some way to purify the water to remove anything that may be left over. All of these things would be best to be collected in a container of some sort in layers of materials.
