

Element D

The process for generating and comparing possible design solutions was comprehensive, iterative, and consistently defensible, making a viable and well-justified design highly likely; the design solution ultimately chosen was well-justified and demonstrated attention to all design requirements; the plan of action has considerable merit and would easily support repetition and testing for effectiveness by others.

The general design of the mirror was largely based off of what the given request of the stakeholder at the time. The stakeholder contributes to what our group designated as the design criteria. As listed in Element C, the criteria then largely contributed to the prototyping of our solution, which proved the credibility of our concept, then assisted in the making of the final product. A large portion of the prototype depended on the level of knowledge our group possessed at the time as to what best fits our criteria, where each member of the group would create three to four concepts, put into a pool of concepts, and voted by the rest of the group to judge which followed the criteria best and so on. As a result, we decided on a model that reflected the criteria best: a ring of LED lights reflected by a mirror which then passes through a diffuser before displaying a glowing effect.

To reiterate, our group did not have a decision matrix, any outside voice or factor, nor a well-justified way of choosing a design when we first began. We quickly came to realize that it may not have been the best choice, but now we know and reflect that we needed a better and more appropriate record of why we chosen a specific design.
