

Element D

The process for generating possible designs and solutions for the rose design, we first identified possible limiting factors, needs, wants, and problems that we would have to work with, or passed. After gathering a list, we began to brainstorm potential solutions, first individually, such as electro magnets, hooks, or adhesives to drop the petals. After individually coming up with ideas, we began to run through potential pros and cons of designs we came up with, weighing them against one another. The concept of having a rose that drops petals remotely, was requested by Mrs. Moody, however, due to the fact it isn't a necessity, and the fact we couldn't find an affordable way to get it done within our time limit, we had to find different ways of dropping petals on command. This effectively eliminated electromagnets from our discussion and narrowed our design down to only a few options, from which we picked hooks, due to their easily reusable design as well as the abundance of string available for us to use. This alongside our lack of ordered resources made the choice to use hooks and string, both necessary and optimal. Then we designed a model that would theoretically drop the roses attached to hooks. We then made a practical model, and tested the individual hook to much success.
