

## **Element E: Application of STEM Principles and Practices**

During this project I used mostly used different websites on google and researched different water filters that were previously built. This would help to determine what did and didn't work so I could improve it. Doing this I could narrow down what I needed to make the filter and how likely it would be to work.

By using rocks as the top layer it can filter out all of the big sticks and other things that dont need to be in the water. The charcoal would help get rid of contaminates and continue getting thing out of the water. The sand would help filter out smaller things and keep geting more and more things out of the water. The cotton and cloth at the bottom would get the smallest things out of the water and get all of the dirt that was left over out. This design would be relatively simple and be a easy way to be sure to get all of the debri out of the water. It wouldn't however be the best to ensure that all of the contaminates get filtered out.
