

The squares below are the Inkscape sketches we did for cutting the acrylic slabs. Here we have two options, which we have tested in the laser cutter. The first option was our first idea, but after testing it we realized the tiles tied on a string will not sit flat because they are not as heavy. We came up with a solution of adding more tiles to the bottom of the whole string, but this wouldn't work, because the tiles would still sit weirdly because of the one knot. The second block is our final option. We chose this because we can easily thread the string through and tie it to each side of the string, making it lay flat while in mid-air. If there are issues with the lightweight tiles not laying flat, we could add a weight at the end of each string, so it would lay regularly. This could be a fishing weight or any heavier item we are able to tie to the string.

This was our original design however, we decided to limit the strings to be 6 x 4. This is because we have to install a screw in each attachment, and it is far more practical to use less strings. It also takes a full class to make one string, so we overestimated how many we could make. We also ended up laser cutting a 12 x 21 grid to maximize the material

(used the green one)

- It has 144 of the boxes shown in the red
