

Element F**Design Viability:**

Design Requirement	Risk Assessment	Risk Mitigation
Changes color manually and automatically	A color-changing pattern that is too fast or too slow could potentially not provide adequate visual sensory for the students. Also, not having manual color-changing ability could limit teachers' and students' ability to express themselves in the classroom.	The fiber optic device that our board utilizes comes with a pre-programmed remote, which gives users the ability to choose the color. This eliminates any of the potential risks caused by static fiber optic lights. Furthermore, if the teachers happen to lose the remote or it gets damaged, they can download an app on their iphone which directly connects to the lights.
Provides calming effects	The device could be overstimulating or understimulating and negatively impact the children's experience.	If the rate-of-flashing is too fast or too slow, the teachers can use their iphone or the remote to manually change the speed to suit the students' needs. Additionally, the fiber optics have the ability to twinkle, which provides another way to engage the students' visual sense. Moreover, teachers can make custom patterns for the fiber optics to cycle through depending on the students' wants or needs.
Illuminates the sensory room	The lights could be too bright or too dim and detract from the overall lighting of the sensory room.	The remote control that controls the display on the fiber optic lights can be adjusted to fit the environment and lighting in the room. The remote can be used to change the level of illumination of the wave board. Teachers / aids should know how to use the remote and control the illumination of the sensory board.

Brightness can be altered	Room could be too bright to notice a difference in brightness.	Make sure the teachers/aids know how to operate the remote to change the brightness. Turn off/on the overhead light in the sensory room depending on if they want the fiber optics to be brighter or darker.
Integrated into the room	The device could take up too much space and not fit cohesively into the sensory room	If the fiber optic wave board takes up too much space in the sensory room or becomes too much of a distraction or overstimulating, the device will be easily installable and removable from the sensory room.
