

- We are conducting several trials with the chariot using its original wheels, timing each run to establish our average time. Once we replace the wheels with the new ones, we will conduct the same number of trials with the same individuals, aiming for consistency. Finally, we will compare the time of the old wheel trial to the time of the new wheel tire to determine if the new wheels yield a faster time.
- We improved on an existing model and tested it. We got wheels from a tire shop, took off the existing wheels, and added the new ones to make our prototype. That prototype became our final prototype because those wheels made it easier to pull and made the chariot faster because of the better tread.
- We had bought wheels from Amazon but ruled them out before we even put them on the chariot. We tested to see if the wheels would be able to roll, but they failed to do so. They were also heavier than the ones from the tire shop which was a con. Along with that, there was an issue with the axle size of the Amazon wheels and the size of where the axle would go on the chariot. The tread of these tires vs the tire shop ones was less which is another reason we ruled them out.
