

Element G

Our final rose prototype consisted of these elements working from the top up. It has a wooden circle base with a hole drilled through the middle. There is then a PVC pipe going slightly through the hole to balance it vertically. That pipe has clay modeled around it to make it more lifelike and the whole stem apparatus is painted green. There is then a cup at the top of the stem with a hole drilled into the bottom as a gateway to the inside of the pipe, this is also painted green. The cup then has 12 small holes drilled into it for the paper clips to slide in and out. The paper clips have the outermost edge folded or to about a 90 degree angle to slide into the holes in the cup. These paper clips are tied to fishing lines which are fed through the cup, pipe, and base to the underside of the whole mechanism to be able to be pulled out. The rose petals were glued on top of each other, staggered vertically to create a larger and more durable petal. The petals are then pushed onto the paper clips through a small hole in the pedal to fasten them onto the stem of the flower. Objective data for our rose includes: visibility of the petals dropping from the front and back of the auditorium, ability to pull the petals off with the strings under the rose, and petal ability to stay off the flower long enough to be cued to be pulled off. If the current prototype passes all of these tests, then the design will pass all of our written criteria and it will be ready to present to Mrs Moody.
