

Element H

Our testing plan consists of accessibility, educational value, safety, and sustainability. Although scale and size is a high priority design requirement, the scale and size will not change from week to week, so testing of that design priority is not necessary. We will test accessibility by measuring week by week the amount of students who experience an accessibility issue, and we will require them to provide a description of their issue when they report one. This will allow us to improve the accessibility of the aquaponics project and we will have our reported number of accessibility issues go to 0 eventually. Next is educational value, which will be tested by measuring the average grades of students who are exposed to the project and comparing it to the average grades of similar students in the past who weren't exposed to the project. Safety will be tested similarly to accessibility, as students who experience an injury or are exposed to one will be required to report it and provide a description along with their report. Lastly is sustainability, which will be tested by measuring the amount of dollars spent per week on resources and materials that had to be replaced.

Our first field expert to review this was Mr. Rickert, who said this was a good idea, but could be improved by adding a QR code to the side of the project to allow the students and teachers to provide their feedback directly to us. He mentioned that one of us goes to visit the project weekly to look over the project and make sure no safety hazards are present, along with the testing plan mentioned above.

Our second field expert is Tommy Kuhn, who talked mostly about sustainability and adding worms to our dirt. He said this will allow for a system with no bio waste at all, which would allow for it to run completely on its own. He also approved the safety and accessibility plans, as well as agreeing with Mr. Rickert on the QR code idea.
