

Element H: Prototype Testing and Data Collection Plan

After the prototype was finished being built it was time to test it and see how well it worked. For the first time testing it I slowly poured dirty water into it and then left it sitting on a table to allow it to have time to filter. I would end up filtering it twice which got more of the color out of the water but it still wasn't clear. The water that came out of the filter came out being a yellow color and did not look so good. If the water would have went through more times it might have gotten more clear but the idea was to make it come out clear the first or second time after being filtered.

Once the testing was done it was time to see how the results turned out. When I tested the ph of the water that came out of the filter it ended up having a balanced ph of seven. The Ammonia and Nitrate levels however, ended up being a problem. The water ended up having both Ammonia and Nitrate in it which made the water undrinkable. If you did happen to drink the water you would probably experience problems later. In a survival situation this would not be ideal since it would not be safe to drink.
