

Prototype Testing, Element H

As a team, we have successfully created a prototype of our Rose petal falling mechanism which requires a few steps. Essentially, it is a base with a cup at the top and several holes in the cup. In these holes, strings will be fed through and they will be connected to paper clips. These paper clips will be plucked through the rose and thus when a string is pulled through the bottom of the rose stem, the paper clip will detach from the rose and gravity will do the rest. There are two key strategies we have decided on regarding how we are going to test our prototype

Single Petal Testing

- Our first strategy to test our prototype is single petal.
 - Essentially, we are designing one petal with one string and paperclip to pull to get the general idea of the rose across.

Once we finished this round of testing we got feedback from our engineering expert and she said that to help the petals stay on for the full rose test we could try and use some sort of adhesive for the back of the petals to keep the petals on until it is their time.

- Our second test is the fully loaded rose
 - In this test we will set up all of the strings and put all of the petals on the paperclips and attempt to run the rose just like the stage crew would do in the show. We would pull a few petals off, wait awhile and then pull the next petals off. We would keep repeating this pattern until all of the petals came off the rose.
