The snow removal system must clear snow while it is still falling.

In Japan snow is removed continuously to stop it from turning into ice.

Suggested focusing on main roads and bus routes

- The design should use heated roads and sidewalks to melt snow and keep areas safe without heavy plowing.
- Japan uses heated streets and sidewalks to melt snow and keep areas safe without heavy plowing.
- Notes cost limits, focus on high traffic zones.

- The system must use less salt and chemicals.
- Denmark limits salt use to protect the environment which helps reduce damage to roads and waterways.
- Suggests combining with mechanical snow removal.

- The design must clear bike lanes as important transportation routes and clears them early during snowstorms.
- Denmark treats bike lanes as important transportation routes and clears them early during snowstorms.

- Agreed bike lanes improve safety and encourage prioritizing protected lanes.
- The snow removal system must work well on narrow, crowded city streets.

Both Japan and Denmark design snow-removal systems for dense cities, which is important for a place like NYC.

- The snow removal system must clearly communicate snow clearing schedules and street conditions to the public.
- Japan uses clear public communication during snowstorms so people know when and where roads will be cleared.
- Shared this idea with NYC residents, who said alerts would help them plan travel and parking, leading to the idea of using text alerts or city apps.
- The design must allow for quick storage or removal so piles do not block sidewalks or intersections.
- In Japan and Denmark, snow is quickly moved or melted to prevent buildup in tight spaces.
- Snow piles might block strollers or curb ramps so definitely need fast removal from corners.
