

Engineering Design Process Summary (K1, K2)

Our design process started off by figuring out what we wanted to solve. The problem was a leaky shower head and how to stop build up within the shower head. The thing that went well would be deciding on the problem. Something that didn't go very well was our time management on getting this done. We decided to make many different drawings to figure out all the possible solutions. We actually were able to agree on a design very quickly and that worked. Our ideas were all very ambitious and kind of undoable which would have been something that went wrong. Our prototype design came straight from our initial drawing. We met and figured out which parts would be the most efficient. What worked is that we reached a consensus very quickly. What did not work again would be the ambitions we had. We were unfortunately not able to build our prototype but we had a clear idea and everything lined up to make it happen. Since we did not get around to building it, we also were not able to test for flaws. Our evaluation was that our team worked very well together and the possible stakeholders were all going to have some type of benefit from this project.

Lessons Learned About the Engineering Design Process (K3)

Designers should consider opportunity costs when it comes to building a functioning prototype. We obviously did not consider how big this project actually was and that set us back in the end. If this were to happen on a larger scale, it would have been nicer to have better time management and less wasted opportunities.
