Reflection on the Design Project

Even though a final design was not created we were still able to test and gain valuable information from testing materials as containers. We learned that the humidity level inside the cigar box was 57% and outside was 70%. This proves that the cigar box has the materials that will work best at keeping the humidity out and inside the box cool. The humidity level for inside the lunch box and bubble wrap foil was 61% and outside 70%. The lunch box had the second best results in this test. The inside of the box still stays relatively cool. The zip lock inside sensor was 62% while the outside 70%. The tupperware's inside sensor was 64% and the outside sensor remained at 70%. And lastly, the metal bottle had an inside sensor of 66% and the percentage of the outside sensor was 70%. The higher the percentage is, that the more humid the surrounding area is. The lower the percentage the less humid and more cooler the air in the container will be. We will use this information to make the final design.
