ELEMENT B

The earliest design attempt at a fire suppression system was the first fire alarm system by Dr. William F. Channing and Moses Farmer in 1859. It was a large machine with several wires and levers, containing a telegraphic key with a metal handle. When a fire was detected, someone would crank the handle, relaying the fire box alarm number to the nearest fire station location. Doing this also sounded the literal alarm, which would ring at the location. Often, if the crank was turned too quickly, the telegraph signal couldn't be sent out. The relationship between the electric current that would pulse out this fire alarm signal and the release of the bell-clappers (the alarm itself) was very touchy and had to be done precisely.

Class: _____

Another significant attempt was the first electrical fire alarm system by Francis Robbins Upton in 1890. While previous telegraphic fire alarms existed, Upton's invention was the first electric system. It utilized electricity to power a mechanism that would detect a fire (usually through heat) and trigger an alarm. Importance of Electricity: The use of electricity made the system faster, more reliable, and easier to operate than earlier mechanical systems that relied on manual pull stations or other mechanisms. It faced challenges in terms of cost and practicality for some applications.

A more recent attempt was the first smoke detector for domestic use by Duane D. Pearsall and Stanley Bennett Peterson in 1965. It was an individual, replaceable, battery-powered unit that could be easily installed. The "SmokeGard 700" was beehive-shaped, fire-resistant, and made of steel. Studies in the 1960s determined that smoke detectors respond to fires much faster than heat detectors.
