

External Evaluation:

We had two instances of external evaluation. The first was the feedback given by Mr. Kiser. He recommended reducing the arm length and moving the mounting point higher. This was recommended because our arm was the majority of our weight issue, so we were able to reduce its weight by shortening it. By moving the connection point higher, we eliminated the need to bend the arm to the floor to reset it, and instead, we reset it at hip level. We also had another engineer come in and give us some advice (I forgot her name), but her main recommendation was how the force would be transferred. She was worried that with the way we had it set up, the pushing force would go down into the bottom of the cart rather than across it. We accounted for this by moving the arm connection point higher on the cart.
