Documentation of Evaluation

After review, other student engineers believed that the suggested prototype could work, with some modifications, such as: holes and battery powered fans placed inside for efficiency. The holes would allow the air to circulate within the box, so the same air wasn't trapped inside for long durations of time. The battery powered fans would allow the prototype to have a cooldown system, in the event that the temperature contained inside of the box became too humid/hot. However, some student engineers have expressed their desire to continue exploring the project in the upcoming school year. They will be doing this under the leadership of an Engineering teacher at Eleanor Roosevelt High School in Greenbelt, Maryland.
