iStar- This Ai tool is a fairly new piece of technology that has been heavily researched and developed by Upenn and what it does interprets medical images with unprecedented clarity does so in a way that it can detect cancer at a much more accurate and faster rate than humans.

Youper- Youper was developed by a company back in 2016 and the Youper AI assistant engages in meaningful conversations with users to gauge their mental state and provides tailored solutions based on the insights . This type of Ai tool could assist heavily with the mental sickness aspect of the medical field.

Projects on AI applications in the medical field begin by the planning of integration of both the ai tolls iStar and Youper into the diagnostic process. The Project objectives would be to effectively and swiftly detect a medical disease that could be life threatening for our patients that could also lower the cost for the patients medical bills. The implementation phase Involves testing the Istar aspect with images and patients' records to determine how effective it could be either detecting a dangerous disease or not. For the mental illness aspect we could use ourselves as a test subject to see if the AI can determine if we are at risk with any mental illness. We have encountered challenges such as ensuring data privacy of the patients because people could be bothered by the risk of allowing AI to have access to medical records. Many ethical concerns could take place too with patience due to the recently developed.
