

## **ELEMENT L**

The advice we would give someone regarding a project similar to ours is to check your measurements plan, before starting the construction of our project we made sure to make a clear plan to know exactly what we would be doing and on what days we would be doing that thing. As a result of our good planning, we were able to successfully construct and make our project function as intended. Spending time sketching and getting the measurement of how all the parts will fit together is a major factor that any engineer or a person trying to replicate a project like ours should take into account and is advice that we prioritize and use throughout our construction. Due to our project only being a prototype, there are still various improvements that could be made in order for it to function more efficiently. Improvements that could be made to our project could start at the wheels. Due to our prototype being used outdoors and indoors, it is important that the wheels can function properly on different terrain without wearing down. Another way to improve this project would be the lever that needs to be pressed for it to carry and dispense the ball. This improvement can greatly affect our prototype as the lever is not being pressed correctly could then cause the balls to not be dispensed or cause a jam. Finally, another improvement that could impact our project would be the wooden rest that our prototype sits on when placed upright. Due to the weight and balance of our prototype, it allows times when it could potentially fall forward especially when loaded with lacrosse balls which is why a bigger rest stand is so important. A plan to fix the improvements on our prototype regarding the lever could include adding rubber bands to the sides, this could allow the lever to retract back inside the prototype every time a ball is dispensed instead of relying on a being. Another plan to improve the improvements of the final prototype is to 3D print or purchase all-terrain wheels.
