

Element I: Testing, Data Collection and Analysis

To test how stable it was at standing up I just sit it on a table and it didn't fall over and was able to stand without being held or having anything to lean on. To test the ph of the water I took a testing strip and swirled it around in the water for two minutes and then looked at what color it turned to determine the ph. To test the Ammonia and Nitrate I used a testing kit that would involve putting some of the water into small tubes and then putting drops of the testing fluid of either the ammonia or nitrate test into one of the tubes then seeing what color the water turned. For ammonia the greener the water turned, the more ammonia that was in the water. When testing the nitrate the more red the water turned, the more nitrate that was in the water. This is how I determined that the water had the right balanced ph but had ammonia and nitrate so it was not drinkable.
