

Element A:

A family is going on a vacation but their child has paruresis. This means that the child is unable to use the bathroom when in sight of another person because they are too shy. The child also cannot lock the door on their own, so a parent must help them lock it. The average child uses the bathroom 5 times a day, at random times, and these places will be diverse (Nashville airport, Colorado airport, Denver mountains, California airport, Disneyland). This poses an enormous issue to the family because the child will have to use the restroom five times a day. Thus, the problem is recurring. This problem most greatly affects the parents and bathroom stall (primary stakeholders). Other people in line are secondary stakeholders because they do not want to see the child peeing, and if the lock takes a long time to attach they will be annoyed by the long wait in line. Another primary stakeholder is the child, as the product is made for their benefit. Solving the problem will make the trip more enjoyable for the family because they will spend less time using the restroom and more time having fun together. Science directly addresses how not only is this a problem in the present, it can have lasting effects on social development if not addressed soon. It is imperative that this problem is solved immediately.¹
